Signing the key assertion — operator sheet (one short sitting)

YubiKey A signs one git commit that names the window's two service keys and dates. The NUC built the commit; the script checks its exact form, shows you the keys and dates it names, and signs only if you type `yes`.

What your signature does and does not mean. It authorizes these two service keys for this window, in the root's name. It does not prove who holds them: their fingerprints come from the owner (the NUC), and the root cannot check them independently. Compare them **in full** with the values the owner gives you: - kms: `spki-sha256: a33c216e 4151f720 2b4863f9 edebf060 b374ee1b b91ff9ca 5734b8e7 ba75679f` - gpg: `gpg-sha256: 6a2d7e75 7b99b46e 469dd81f 293387b7 cfdbe3a1 cab2b614 dd2d26ec c79dda59`

Sticks: **INPUT** and **OUT**, both never in the NUC (the reformatted purple rehearsal sticks will do). [**PHOTO**] = photograph the screen. Nothing secret appears on screen except the PIN prompt.

1. Fetch (a networked Tails boot)

The owner names a commit and three SHA-256 values: `sign-assertion.sh`, `payload.txt` and `root.pub.asc`.

```
git clone https://github.com/fsgeek/tessera.git
```

```
cd tessera
```

```
git checkout <the commit>
```

```
sha256sum docs/ceremony/sign-assertion.sh docs/ceremony/assertion/payload.txt docs/ceremony/
```

All three must equal the owner's values. Format INPUT (FAT, volume name `INPUT`), open it in *Files*, then:

```
cp docs/ceremony/sign-assertion.sh docs/ceremony/assertion/payload.txt docs/ceremony/asserti
```

Eject; shut down.

2. Sign (an offline Tails boot)

Network off. Insert INPUT and OUT (format OUT: FAT, volume name `OUT`); open both in *Files*. Not YubiKey A yet.

```
cp /media/amnesia/INPUT/sign-assertion.sh /tmp/s.sh
```

```
sha256sum /tmp/s.sh
```

Same as the owner's value. Read it (`less /tmp/s.sh`). Then:

```
bash /tmp/s.sh
```

[**PHOTO**] the `FORM OK, TREE MATCH` block. Compare both fingerprints in full with the ones above, and the two dates with the owner's. If they are right, type `yes`, insert YubiKey A when asked, enter the PIN, touch when it blinks. Want `==> PASS`. [**PHOTO**]. Eject both sticks, remove YubiKey A, shut down. OUT goes to the owner.

If anything fails: nothing has been signed or changed on the card. Photograph it and stop.
